## PYRROLIDINE DERIVATIVES AS INHIBITORS OF ENDOTHELIN-CONVERTING ENZYME

Pyrrolidine Derivatives

The present invention is directed to compounds which are useful as inhibitors of metalloproteases, e.g. zinc proteases, particularly zinc hydrolases, and which are effective in the prophylaxis and treatment of disease states which are associated with vasoconstriction of increasing occurrences. Examples of such disorders are high blood pressure, coronary disorders, cardiac insufficiency, renal and myocardial ischaemia, renal insufficiency, dialysis, cerebral ischaemia, cardiac infarct, migraine, subarachnoid haemorrhage, Raynaud syndrome and pulmonary high pressure. In addition the compounds are useful as cytostatic and cerebroprotective agents for inhibition of graft rejection, for organ protection and for treatment of ophthalmological diseases.

Endothelins are peptides, that exist in three isoforms ET-1, ET-2, and ET-3, each encoded by a distinct gene. They have been originally discovered in the conditioned medium of porcine endothelial cells in 1988 by Yanagisawa (Yanagisawa M; Kurihara H; Kimura S; Tomobe Y; Kobayashi M; Mitsui Y; Yazaki Y; Goto K; Masaki T: A novel potent vasoconstrictor peptide produced by vascular endothelial cells [see comments]. NATURE (1988 Mar 31), 332(6163), 411-5.). The active ETs are peptides of 21 amino acids with two intramolecular disulfide bridges. They are produced from preproproteins of 203 to 212 amino acids which are processed by furin like endopeptidases to the biologically inactive big-endothelin (big-ET). The big-ETs are specifically processed to mature ETs by a hydrolytic cleavage between amino acids 21 and 22 that are Trp<sup>21</sup>-Val<sup>22</sup> (big-ET-1, big ET-2) and Trp<sup>21</sup>-Ile<sup>22</sup> in big-ET-3 respectively. Already in 1988 a specific metalloprotease was postulated to be responsible for this specific cleavage. In 1994 ECE-1 (endothelin converting enzyme-1) was purified and cloned from bovine adrenal (Xu D, Emoto N, Giaid A, Slaughter C, Kaw S, de Witt D, Yanagisawa M: ECE-1: a membrane-bound

- 2 -

metalloprotease that catalyzes the proteolytic activation of big endothelin-1. Cell (1994) 78: 473 – 485.).

ECE-1 is a membrane bound type II zinc-endopeptidase with a neutral pH optimum and a zinc binding motif HExxHx(>20)E. It belongs to subfamily M13 and has a large 681 amino acid ectodomain that comprises the active site. Other members of the M13 family are NEP24.11 (neutral endopeptidase), PEX, a phosphate regulating neutral endopeptidase, and Kell blood group protein that has recently been described as a big-ET-3 processing enzyme. Members of the M13 family of human origin are characterized by a high molecular weight (> 80 kDa) a number of conserved disulfide bridges and a complex glycosylation pattern. The structure of NEP has recently been solved. (Oefner et al, J. Mol. Biol. 2000, 296, 341-349). The catalytic domain of ECE and related human M13 proteinases are significantly larger (>650 amino acids) than members of matrix metalloproteases (MMPs). Unlike the family of the MMPs which belong to the metzincins and display a typical HExxHxxGxxH pattern members of the M13 family are gluzincins comprising a HExxHx(>20)E pattern. These two families are clearly different in size of catalytic domains, structure and zinc coordinating pattern of ligands. Active sites of the two families show clear differences which has clear impact on type of inhibitors and the potential selectivity.

One aspect of the invention is directed to compounds of general formula I

The invention also refers to the above compounds whenever manufactured by a process as described below.

Compounds of formula (I) can be prepared by methods known in the art or as described below. Unless indicated otherwise, the substituents  $R^1$ ,  $R^2$ ,  $R^3$ ,  $R^4$ ,  $R^5$ ,  $R^6$ ,  $R^7$ ,  $R^8$ ,  $R^9$ ,  $R^{10}$ ,  $R^{11}$ ,  $R^{12}$ , A, m, X and Y are as described above.

The synthesis of the intermediates (acids) for the preparation of compounds of the formula (I) are depicted in Scheme 1. The starting material is commercial available or is synthesized from hydroxyproline by methods known in the art and described for example in "The Practice of Peptide Synthesis", M. Bodanszky and A. Bodanszky, Springer Verlag, Berlin, 1984.

Step a of Scheme 1 describes the persilylation of hydroxy- and amino groups, e.g. by reaction of compound 1 with hexamethyldisilazan at 140°C followed by reaction with  $R^2SO_2Cl$  in THF or conversion to all other  $R^2X$  described later or di-t-butylidicarbonate,  $NaHCO_3$  in dioxane,  $H_2O$  (BOC protection).

For inversion of the configuration (via mesylate) the resulting alcohol 2 is treated with  $MeSO_3H$ ,  $Ph_3P$ , DIAD or DEAD in toluene (room temperature to 80°C) or (via bromide) with  $LiBr$ , DEAD,  $Ph_3P$  in THF (4°C to room temperature) or (via chloride) with  $Ph_3P$ ,  $CCl_4$  in  $CH_2Cl_2$  (3°C to room temperature). In the case of retention of the configuration (via mesylate or tosylate) alcohol 2 can be transformed to a compound of formula 3 by reaction with  $MeSO_2Cl$ , pyridine, DMAP or  $TosCl$ , pyridine, DMAP in  $CH_2Cl_2$  (0°C to room temperature).

For the introduction of a protected thiol moiety, compounds of formula 3 are treated with e.g. triphenylmethanethiol or 4-methoxybenzylmercaptane and K-Ot-Bu in DMF (for Br: 0°C to room temperature; for Cl: 0°C; for Mesylate: room temperature to 100°C) or with potassium thioacetate in DMF room temperature to 100°C (step c).

- 5 In the case of  $X-R^2 = \text{BOC}$  and  $R \neq t\text{-butyl}$ , BOC deprotection can be accomplished with TFA in  $\text{CH}_2\text{Cl}_2$  at  $-20^\circ\text{C}$  to room temperature to give an amine. For the introduction of a new  $R^2$ , the amine may be reacted with  $R^2\text{OCOCl}$ /pyridine in THF or with (a)  $R^2\text{OH}/\text{Cl}_3\text{COCl}$ /quinoline (formation of the chloroformate) followed by reaction with NaH, in case new  $R^2X$  is a carbamate. In case  $R^2X$  is a sulfonamide the amine may be  
10 treated with  $R^2\text{SO}_2\text{Cl}$ ,  $(i\text{-Pr})_2\text{EtN}$ , optionally in the presence of catalytic DMAP or DMAP-poly. in  $\text{CH}_2\text{Cl}_2$  at room temperature or in case  $R^2X$  is amide the amine may be reacted with  $R^2\text{COOH}$ , EDCI, DMAP.

- Hydrolysis of ester 4 (PG= Acetyl, step d) can be achieved with aqueous lithium hydroxide in THF ( $0^\circ\text{C}$  to RT) or sodium hydroxide in ethanol to give acid 5, in the case of  
15 t-butyl esters the saponification can be accomplished with TFA in  $\text{CH}_2\text{Cl}_2$ .

- For the reaction of compound 5 to compound 6 (step e) the Arndt-Eistert reaction may be used. Therefore in the case  $m = 1$  the following procedure is used: addition of  $(\text{COCl})_2$ , cat DMF in  $\text{CH}_2\text{Cl}_2$  at  $0^\circ\text{C}$  to room temperature to give the corresponding acid chloride followed by reaction with trimethylsilyldiazomethane in THF,  $\text{CH}_3\text{CN}$  at  $0^\circ\text{C}$  to  
20 room temperature to give the corresponding diazoethanone and rearrangement to the methyl ester with silver benzoate in MeOH, THF at  $-25^\circ\text{C}$  to room temperature, followed by ester cleavage with aqueous lithium hydroxide in THF ( $0^\circ\text{C}$  to RT) or sodium hydroxide in ethanol to give compound 6. For  $m = 2$  compounds of formula 5 can be transformed into the corresponding Weinreb amide (e.g.  $\text{HCl}\cdot\text{HNMeOMe}$ , NMM, EDCI, HOBT) and  
25 can be converted to an aldehyde (LAH,  $-78$  to  $-30^\circ\text{C}$  in THF). The obtained compound can be converted by a Horner-Emmons reaction (e.g.  $(\text{EtO})_2\text{P}(=\text{O})\text{CH}_2\text{COOEt}$ , NaH in THF) followed by reduction of the double bond (e.g. Mg in MeOH) and saponification of the ester with either aqueous lithium hydroxide in THF ( $0^\circ\text{C}$  to RT) or sodium hydroxide to give compound 6.
- 30 BOC replacement against other  $R^2X$  may follow by BOC-cleavage and treatment of the amine with the reagents described above.

Starting from the S-acetyl protected ester 4, saponification of the ester and the thioester moiety with 0.1M LiOH in THF or 1M NaOH in THF gives the thiol, which is

- 17 -

treated with iodine and triethylamine or  $i\text{Pr}_2\text{NEt}$  in  $\text{CH}_2\text{Cl}_2$  to yield the disulfid-diacid 7 (step f, scheme 1).

The side chain A can be readily assembled as depicted in Scheme 2a prior to the coupling to the acids which were prepared according to scheme 1. A suitably protected aminoacid is treated with TPTU, 4-Methylmorpholine in  $\text{CH}_2\text{Cl}_2$  and the appropriate amine  $\text{NHR}^{10}\text{R}^{11}$ , or with 2-chloro-4,6-dimethoxy-1,3,5-triazine, 4-methyl-morpholine, 5 amine  $\text{NHR}^{10}\text{R}^{11}$  and 4-dimethylamino-pyridin in DMF. Alternatively, the amide 2 can be prepared by transferring the acid 1 into the corresponding chloride (e.g. oxalyl chloride in toluene) or into the corresponding mixed anhydride (e.g. isobutyl chloroformate and N-ethylmorpholine in DMF) followed by treatment with the desired amine  $\text{NHR}^{10}\text{R}^{11}$  in DMF.

10 Deprotected amine 3 can be obtained (step b) in the case of BOC-protection by treatment with TFA in  $\text{CH}_2\text{Cl}_2$  and in the case of Z-protection by hydrogenation (e.g. 10%Pd/C,  $\text{H}_2$  in MeOH in the presence of HCl or 10%Pd/C,  $\text{H}_2$  in MeOH/ $\text{NEt}_3$ ).

Further modifications of the side chain may be achieved prior to deprotection: An ester moiety at the aromatic ring ( $\text{R}^a$ ) may be reduced to the hydroxymethyl group on 15 treatment with lithium borhydride in THF (50°C, 2h, step c). This may be protected as a TBDMS ether using TBDMSCl and imidazole in DMF, 12 h, 5°C to room temperature (step d) or transferred into an ether by treatment with sodium hydride, alkyl iodide in DMF (step e).

Other amines may be prepared using the route outlined in Scheme 2b: namely the 20 alkylation of the amine 4 with the bromo derivative 5 gives the corresponding secondary amine 6 (step f).

### SCHEME 3

- 22 -

Compounds of the formula (I) can be prepared as depicted in Scheme 3 from the acid 1 and a corresponding amine  $\text{HNR}^5\text{R}^6$ . For the synthesis of thio protected amide 2 several methods may be employed: TPTU, NMM or  $\text{iPr}_2\text{NEt}$ ,  $\text{HNR}^5\text{R}^6$  in  $\text{CH}_2\text{Cl}_2$  or EDCI, HOBT,  $\text{HNR}^5\text{R}^6$  in THF, transformation of the acid into the corresponding chloride (e.g. oxalyl chloride in DMF) or into the corresponding mixed anhydride (e.g. i-propyl- or ethyl chloroformate in DMF) followed by treatment with  $\text{HNR}^3\text{R}^4$  in DMF (step a).

Deprotection of the thio moiety (step b) may be achieved in the case PG is either p-methoxybenzyl or trityl using triethylsilane in TFA, or triisopropylsilane in TFA, for PG is acetyl using lithium hydroxide in THF/water or sodium alkoholates in THF.

In the case PG is the homodimer, disulfide cleavage with tri-n-butylphosphine and water in 2,2,2-tri-fluoroethanol or DTT, 2M aq.  $\text{K}_2\text{CO}_3$  in MeOH, THF gives the thiol compound 3.

In the case of  $\text{R}^2\text{X} = \text{BOC}$ , the final  $\text{R}^2\text{X}$  can be introduced by BOC deprotection (e.g. TFA,  $\text{CH}_2\text{Cl}_2$  at  $0^\circ\text{C}$  to room temperature) to get the amine which can be further modified.

In case  $\text{R}^2\text{X}$  is a carbamate this amine may be reacted with  $\text{R}^2\text{OCOCl}$ , pyridine or  $(\text{i-Pr})_2\text{EtN}$  in THF or  $\text{CH}_2\text{Cl}_2$  or by reaction with (a)  $\text{R}^2\text{OH}$ ,  $\text{Cl}_3\text{COCl}$ , quinoline (formation of the chloroformate) followed by reaction with NaH. In case  $\text{R}^2\text{X}$  is a sulfonamide the starting compounds may be reacted with  $\text{R}^2\text{SO}_2\text{Cl}$ ,  $(\text{i-Pr})_2\text{EtN}$ , cat DMAP in  $\text{Cl}_2\text{CH}_2$  at room temperature. In case  $\text{R}^2\text{X}$  is urea the starting compounds may be reacted with isocyanate in EtOH at room temperature. In case  $\text{R}^2\text{X}$  is an alkylated urea the starting compounds may be reacted with isocyanate in EtOH at room temperature followed by reaction with the corresponding alkylhalogenide, K-OtBu at  $0^\circ\text{C}$  to room temperature. In case  $\text{R}^2\text{X}$  is an amide, the starting compounds may be reacted with  $\text{R}^2\text{COOH}$ , EDCI, DMAP (with anhydride formation, and subsequent addition of the starting amine at  $-10^\circ\text{C}$  to room temperature or as alternative with  $\text{R}^2\text{COOH}$ /EDCI/DMAP at room temperature. In case  $\text{R}^2\text{X}$  is a sulfamide (for  $\text{R}^{13}$  is H) the amine may be reacted with sulfamoyl chlorides in dioxane in the presence of an excess of triethylamine. The sulfamoyl chlorides may be synthesized from  $\text{R}^2\text{NH}_2$  and chlorosulfonic acid in  $\text{CH}_2\text{Cl}_2$  at  $0^\circ\text{C}$  to room temperature followed by reaction with  $\text{PCl}_5$  in toluene at  $75^\circ\text{C}$ . Alternatively the sulfamoyl chlorides can be synthesized in acetonitrile with  $\text{R}^2\text{NH}_2$  and sulfuryl chloride at  $0^\circ\text{C}$  to  $65^\circ\text{C}$ . In case  $\text{R}^2\text{X}$  is an alkylated sulfamide ( $\text{R}^{13}$  is not H) the sulfamide  $\text{R}^2\text{SONH-}$  may be reacted with NaH, alkyl halide in DMF at  $0^\circ\text{C}$  to room temperature.

In the cases in which  $R^6$  contains a cyano moiety treatment with triethyl silane in TFA at 0°C to room temperature may give reduction to the amide concomitant to the S-PMB-ether cleavage. Selective thio deprotection may be accomplished with triethyl silane in TFA at 0°C for 15 min. A further modification of the residue at  $R^6$  may be the  
5 transformation of the cyano moiety into a tetrazole by treatment with sodium azide and ammonium chloride in DMF at 70-120°C followed by deprotection as described above (e.g. TFA,  $Et_3SiH$ , reflux).

In the cases in which  $R^6$  is of the formula (II) with  $R^8$  is  $OR^9$ , further modifications of the side chain can be achieved by ester saponification using lithium hydroxide in THF  
10 followed by amide formation with the amine  $HNR^{10}R^{11}$  by one of the methods given before (step c,d, Scheme 3). The compound 5 can be deprotected according to the methods listed above (step e, see step b).

In the cases in which one of the residues  $R^7$  or  $R^{11}$  contains an ester this can be hydrolyzed prior to S-deprotection (for S-PMB or S-Tr ) or for the homodimers using  
15 lithium hydroxide in THF or sodium hydroxide in THF.

A further method for the modification of the  $R^{11}$  comprises the reduction of an ester to a methylhydroxy group (e.g. with lithium borohydride in THF) or the deprotection of an alcohol moiety according to the methods known in the art (e.g. HF acetonitrile,  $CH_2Cl_2$ ). Optionally this alcohol can be alkylated using e.g. sodium hydride, alkyl halogenides in  
20 THF or DMF or tert-Butyl 2,2,2-trichloroacetimidate with triflic acid in  $CH_2Cl_2$ , c-hexane or  $CCl_4$ .

The hydroxy moiety of a tyrosine may be further manipulated by treating the compound 2 in case  $R^{12}Y$  is a sulfonamide with  $R^{12}SO_2Cl$ ,  $(i-Pr)_2EtN$ , cat DMAP in  $CH_2Cl_2$  at room temperature, in case  $R^{12}Y$  is a carbamate with  $R^{12}OCOCl$ , pyridine or  $(i-Pr)_2EtN$  in THF or  $CH_2Cl_2$ , in case  $R^{12}Y$  is urea the starting compounds may be reacted  
25 with isocyanate in EtOH at room temperature, in case  $R^{12}Y$  is an amide, with  $R^{12}COOH$ , EDCI, DMAP at -10 °C to room temperature, in case  $R^{12}Y$  is an ether with reactive alkyl halogenides or arylalkyl halogenides. Deprotection of the thio moiety with triethylsilane, TFA for S-PMB and S-Tr or disulfide cleavage with tri-n-butylphosphine and water in 2,2,2-trifluoroethanol or DTT, 2M aq.  $K_2CO_3$  in MeOH, THF gives compound 7 (steps f, b).  
30 Furthermore, compounds of the formula (I) with A is  $-CONR^5R^6$  may be prepared as depicted in Scheme 4. The acid 1 can be treated with amine  $H_2NR^5$  or  $H_2NR^6$ , EDCI, HOBT in THF or one of the other methods for amide formation described above followed

- 24 -

by deprotection of the thio moiety with triethylsilane in TFA at reflux to give amide 3 (steps a, b). The second substituent may be introduced via alkylation. Therefore amide 2 may be treated with reactive R<sup>5</sup>-halogenides and sodium hydride in DMF to give after S-Tr or S-PMB deprotection with triethylsilane in TFA amide 4. In the case that R<sup>6</sup> contains an  
5 ester,  $\alpha$ -alkylation leads to a modification of the side chain A (e.g. a. LiHMDS, b. R<sup>5</sup>-Br in THF). On deprotection the amide 5 can be obtained (steps d, b).

**SCHEME 4**

### **SCHEME 5**

Tetrazole derivatives may be prepared as depicted in Scheme 5. Acid 1 can be transformed into the amide 2 which contains a tetrazole moiety by treatment with an aminotetrazol, HOBT, EDCI in THF, followed by treatment with DBU in  $\text{CH}_2\text{Cl}_2$  or using one of the methods described above (step b). For the synthesis of the tetrazolamino derivative see for example Sephane De Lombaert, Preparation of tetrazolylalkylaminomethylphosphonates as neutral endopeptidase inhibitors. US 5273990 A 931228 or S. De Lombaert et al J. Med Chem, 2000, 43, 488-504 and literature cited therein. The tetrazole moiety may be protected before introduction of the side chain (e.g.  $\text{PG}^2$  is  $\text{CH}_2\text{CH}_2\text{CN}$ ) or by manipulations of the amide 2 (e.g. 4-methoxybenzylchloride, NaI,  $\text{Et}_3\text{N}$  in acetone).

Alkylation of the amide 2 which contains a  $\text{PG}^2$ -protected tetrazole (e.g. sodium hydride, alkyl halogenide in DMF) gives after deprotection of the thio and the tetrazole moieties (e.g. triethylsilane, TFA,  $80^\circ\text{C}$ ) the compound 3 (steps c,b).

In the case of the unprotected tetrazole derivative 2 ( $\text{PG}^2$  is H) alkylation using sodium hydride, alkyl halogenide in DMF may give a mixture of double alkylated regioisomers which can be separated and deprotected (e.g. triethylsilane, TFA,  $80^\circ\text{C}$ ) to give compound 5 and 6 (step d,b).

Another method for the modification at the residue  $\text{R}^2\text{X}$  is depicted in Scheme 6.

Treatment of the methylsulfonamide derivative 1 with LDA followed by alkylation with e.g. benzylbromide followed by transformation to the amide 2 by treatment with  $\text{NHR}^5\text{R}^6$ , HOBT, EDCI in THF or any other method described above for the amide formation (steps a,b). Dialkylation can be accomplished with LiHMDS, followed by treatment with e.g. benzylbromide followed by transformation to the amide 4. In both cases thiol deprotection may be achieved with triethylsilane in TFA.

An alternative synthetic route is depicted in Scheme 7, in which the amide formation is performed prior to the introduction of the thio moiety. Acid 1 is preactivated with TPTU in  $\text{CH}_2\text{Cl}_2$ , NMM or by treatment with EDCI,  $\text{CH}_2\text{Cl}_2$ , NMM in  $\text{CH}_2\text{Cl}_2$  followed by treatment with the amine  $\text{NHR}^3\text{R}^4$  or by any other amide formation described in the previous schemes. For inversion of the configuration (via mesylate) the resulting alcohol 2 is treated with  $\text{MeSO}_3\text{H}$ ,  $\text{Ph}_3\text{P}$ , DIAD or DEAD in toluene (room temperature to  $80^\circ\text{C}$ ) or (via bromide) with LiBr, DEAD,  $\text{Ph}_3\text{P}$  in THF ( $4^\circ\text{C}$  to room temperature) or (via chloride) with  $\text{Ph}_3\text{P}$ ,  $\text{CCl}_4$  in  $\text{CH}_2\text{Cl}_2$  ( $3^\circ\text{C}$  to room temperature). In case of retention of the configuration (via mesylate or tosylate) alcohol 2 can be transformed to a compound of

formula 3 by reaction with  $\text{MeSO}_2\text{Cl}$ , pyridine, DMAP or  $\text{TosCl}$ , pyridine, DMAP in  $\text{CH}_2\text{Cl}_2$  ( $0^\circ\text{C}$  to room temperature).

Transformation to the corresponding protected thio compound 4 can be achieved e.g. by treatment with potassium thioacetate in DMF.

- 5        If further modification of the  $\text{R}^2\text{X}$  moiety is desired, in the case of  $\text{R}^2\text{X}$  is BOC deprotection can be achieved with TFA in  $\text{CH}_2\text{Cl}_2$  followed by further modification of the liberated amine by treatment with the reagents described for reactions in Scheme 1 and 3.

- Cleavage of the thioester 4 can be achieved by treatment with 0.1M lithium hydroxide in THF or 1M sodium hydroxide in THF (cleavage of all other ester moieties) or  
10    with sodium alkanolate in THF to give compound 5.

SCHEME 8

Ketones and alcohols of formula (I, A = -C(O)-R<sup>3</sup> or -CH(OH)-R<sup>4</sup>) may be prepared as depicted in Scheme 8. In the scheme the group R<sup>3</sup> also includes the definitions for R<sup>4</sup> as mentioned above. The starting acid 1 may be transferred into the Weinreb derivative with  
5 NHMeOMe·HCl, Me<sub>3</sub>Al (excess) in toluene or by pre-activation of acid 1 with TPTU, Huenig's base in DMF at RT followed by reaction with NH(OMe)Me.

In the case of R<sup>2</sup>X= BOC, the final R<sup>2</sup>X can be introduced by BOC deprotection (e.g. TFA, CH<sub>2</sub>Cl<sub>2</sub> at 0°C to room temperature) to get the amine which can be further reacted with one of the reagents described for the compounds in Scheme 1 or 3.

- 10 The Weinreb derivative 2 may be treated with metal organic compounds (e.g. R<sup>3</sup>MgBr in THF or R<sup>3</sup>Li -25°C to RT in THF) to give the S-protected ketones 3. Deprotection may be accomplished by oxidation to the corresponding disulfide employing DMSO, Me<sub>3</sub>SiCl in acetonitril followed by disulfid cleavage with DTT in the presence of potassium carbonate in methanol or with triethylsilane in TFA to give ketone 4.  
15 Deprotection and reduction to the alcohols 5 may be achieved using iPr<sub>3</sub>SiH, TFA in CH<sub>2</sub>Cl<sub>2</sub>.

- For the synthesis of ketones of the type 12 (steps i, b, c), the acid 1 can be transferred into the corresponding Weinreb derivative 10 by pre-activation with TPTU, Huenig's base in DMF at RT followed by reaction with NHR<sup>5</sup>CH<sub>2</sub>NH(OMe)Me. From Weinreb  
20 derivative 10 the desired ketones can be prepared by treatment with metal organic compounds (e.g. R<sup>3</sup>MgBr in THF or R<sup>3</sup>Li -25°C to RT in THF) followed by deprotection using triethylsilane in TFA.

- Alternatively, the alcohols 5 (for m=0) can be prepared from the ester 6 by selctive reduction to the aldehyde 7 (e.g. di-isobutylaluminium hydride in toluene, THF at -78°C  
25 (step e)) followed by treatment with metal organic compounds (e.g. R<sup>3</sup>MgBr in THF or R<sup>3</sup>Li -25°C to RT in THF, step f) to give alcohol 8 as a mixture of diastereomers. In the case R<sup>3</sup> contains a triple bond, this can optionally be reduced (H<sub>2</sub>/ Pd/C in MeOH at 1 atm). For the introduction of the protected thio moiety, compound 8 may be treated with potassium acetate in DMF at 100°C, 2.5 h. After separation of the diastereomers the single  
30 compounds are liberated from the S-Ac prodrugs by treatment with 1N LiOH in EtOH (step h).

For the preparation of compounds of formula (I) the reaction pathway of Scheme 9,10-resin synthesis can be followed: the synthesis of the starting material 1 from hydroxyproline is described in Scheme 1. TFA, triisopropyl deprotection at reflux for 30 minutes gives thiol 2 (step a). The final  $R^2X$  may be introduced either before attachment to the resin or after the preparation of the ketone on the resin (Scheme 10). For the second case,  $R^2X$  ideally comprises Fmoc. This may be prepared from  $R^2X$  (=BOC) of starting acid 1 by methods known in the art and described for example in "The Practice of Peptide Synthesis", M. Bodanszky and A. Bodanszky, Springer Verlag, Berlin, 1984 to a nonacid labile protecting group (e.g.  $R^2X$  = Fmoc, first selective BOC-deprotection with 40% TFA in  $CH_2Cl_2$  at RT followed by reaction with Fmoc-OSu in dioxane/water and  $NaHCO_3$  as base).

The resin may be prepared as follows (step b, Scheme 9): The linker 4-( $\alpha,\alpha$ -diphenylhydroxymethyl)benzoic acid is activated using TPTU, diisopropylethylamine in DMF and added to benzhydrylamine resin 3. The resin 4 is then treated with thiol 2 in  $CH_2Cl_2$ , TFA to give the resin loaded starting material 5.

The synthesis of final compounds of formula (I) is shown in Scheme 10: The resin linked acid 1 is transformed into the corresponding Weinreb derivative 2 by pre-activation of acid 1 (TPTU, Huenig's base in DMF at RT) followed by reaction with  $NH(OMe)Me$ . The compound 2 is treated with metal organic compounds of type  $R^5MX$  to give the resin bound ketones 3 which can be detached by treatment with TFA,  $iPr_3SiH$  in  $CH_2Cl_2$  at RT (step d).

Further modification of  $R^2$  can be accomplished in the case of  $R^2X$  = Fmoc before detaching the compound of the resin. Therefore, the Fmoc protected compound 2 is treated with 20% piperidine in DMF, followed by introduction of the new  $R^2X$  by the methods described for synthesis in Schemes 1 and 3.

**SCHEME 9**

**SCHEME 10****SCHEME 11**

Preparation of prodrugs (Scheme 11) may be accomplished by treating the thiols 1 with the corresponding anhydrides or acid chlorides (e.g. Ac<sub>2</sub>O/pyridine in CH<sub>2</sub>Cl<sub>2</sub> at room temperature or AcCl/ pyridine in CH<sub>2</sub>Cl<sub>2</sub>(step a)). If the residue A contains a  
5 carboxylic acid moiety this can be transferred into an ester (e.g. alcohol, EDCI, DMAP, CH<sub>2</sub>Cl<sub>2</sub>, step b).

Disulfide derivatives may be prepared by treating the thiol 1 with Ac-Cys(NPys)-OH in DMF as depicted in step c.

On the basis of their capability of inhibiting metalloprotease activity, especially  
10 zinc hydrolase activity, the compounds of formula I can be used as medicaments for the treatment and prophylaxis of disorders which are associated with vasoconstriction of increasing occurrences. Examples of such disorders are high blood pressure, coronary disorders, cardiac insufficiency, renal and myocardial ischaemia, renal insufficiency, dialysis, cerebral ischaemia, cardiac infarct, migraine, subarachnoid haemorrhage,  
15 Raynaud syndrome and pulmonary high pressure. They can also be used in atherosclerosis, the prevention of restenosis after balloon-induced vascular dilation, inflammations, gastric and duodenal ulcers, ulcer cruris, gram-negative sepsis, shock, glomerulonephritis, renal colic, glaucoma, asthma, in the therapy and prophylaxis of diabetic complications and complications in the administration of cyclosporin, as well  
20 as other disorders associated with endothelin activities.

The ability of the compounds of formula (I) to inhibit metalloprotease activity, particularly zinc hydrolase activity, may be demonstrated by a variety of in vitro and in vivo assays known to those of ordinary skill in the art.

#### 25 A) Cell Culture

A stable human umbilical vein endothelial cell line (ECV304) was cultured in "cell factories" as described until confluency (Schweizer et al. 1997, Biochem. J. 328: 871-878). At confluency cells were detached with a trypsin / EDTA solution and collected by low speed centrifugation. The cell pellet was washed once with phosphate buffered  
30 saline pH 7.0 and stored at -80 °C until use.

- 37 -

### B) Solubilization of ECE from ECV304 cells

All procedures were performed at 0-4°C if not stated otherwise. The cell pellet of  $1 \times 10^9$  cells was suspended in 50 ml of buffer A (20 mM Tris/HCl, pH 7.5 containing 5 mM  $MgCl_2$ , 100  $\mu M$  PMSF, 20  $\mu M$  E64, 20  $\mu M$  leupeptin) and sonicated. The resulting  
5 cell homogenate was centrifuged at 100,000  $g_{av}$  for 60 minutes. The supernatant was discarded and the resulting membrane pellet was homogenized in 50 ml buffer A and centrifugated as described. The washing of the membrane fraction in buffer A was repeated twice. The final membrane preparation was homogenized in 50 ml of buffer B (buffer A + 0.5% Tween 20 (v/v), 0.5% CHAPS (w/v), 0.5% Digitonin (w/v)) and  
10 stirred at 4°C for 2 hours. Thereafter the remaining membrane fragments were sedimented as described. The resulting clear supernatant containing the solubilized ECE was stored in 1.0 ml aliquots at -120°C until use.

### C) ECE Assay

15 The assay measured the production of ET-1 from human big ET-1. To measure high numbers of samples an assay performed in 96 well plates was invented. The enzyme reaction and the radioimmunological detection of the produced ET-1 was performed in the same well, using a specifically developed and optimized coating technique.

20

### D) Coating of Plates

Fluoronunc Maxisorp White (code 437796) 96 well plates were irradiated with 1 joule for 30 minutes in a UV Stratalinker 2400 (Stratagene). The 96 well plates were then fill with 300  $\mu l$  protein A solution (2  $\mu g/ml$  in 0.1 M  $Na_2CO_3$  pH 9.5) per well and  
25 incubated for 48 hours at 4°C. Coated plates can be stored for up to 3 weeks at 4°C until use.

Before use the protein A solution is discarded and the plates are blocked for 2 hours at 4°C with 0.5% BSA in 0.1M  $Na_2CO_3$ , pH 9.5.

Plates were washed with bidistilled water and were ready to perform the ECE  
30 assay.

### E) Screening assay

Test compounds are solved and diluted in DMSO. 10 µl of DMSO was placed in the wells, followed by 125 µl of assay buffer (50 mM Tris/HCl, pH 7.0, 1 µM Thiorphan, 0,1% NaN<sub>3</sub>, 0.1% BSA) containing 200 ng big ET-1. The enzyme reaction was started by the addition of 50 µl of solubilized ECE (diluted in assay buffer 1:30 to 1:60 fold (v/v)). The enzyme reaction was carried out for 30 minutes at 37°C. The enzyme reaction was stopped by addition of 10 µl 150 mM EDTA, pH 7.0.

### 10 Radioimmunoassay:

The ET-1 RIA was performed principally as described earlier (Löffler, B.-M. and Maire, J.-P. 1994, Endothelium 1: 273-286). To plates containing the EDTA stopped enzyme reaction mixture 25 µl of assay buffer containing 20000 cpm (3-(<sup>125</sup>I)Tyr)-endothelin-1 and 25 µl of the ET specific antiserum AS-3 (dilution in assay buffer 1:1000) was added. Plates were incubated under mixing at 4°C over night. Thereafter, the liquid phase was sucked with a plate washer and plates were washed once with bidestilled water. To the washed plates 200 µl scintillation cocktail (Microscint 40 LSC-Cocktail, Packard, code 6013641) was added and plates were counted for 2 minutes per well in a Topcount.

20

Standard curves were prepared in plates with synthetic ET-1 with final concentrations of 0 to 3000 pg ET-1 per well. In all plates controls for maximal ECE activity (in the presence of 10 µl DMSO) and for background production of ET-1 immunoreactivity (in the presence of 10 mM EDTA or 100 µM phosphoramidon) were performed. Assays were run in triplicate.

25

### F) Kinetic Assay

The described assay format could be used to determine the kinetic characteristics of the used ECE preparation as well as different ECE inhibitors (i.e.  $K_m$ ,  $K_i$ ) by variation of the substrate concentration used in the assay.

5

### G) Cell based ECE Assay

Human ECE-1c was stable expressed in MDCK cells as described (Schweizer et al. 1997, Biochem. J. 328: 871-878). Cells were cultured in 24 well plates to confluency in Dulbecco's modified Eagles's medium (DMEM) supplemented with 10 % (v/v) fetal  
10 bovine serum (FBS) , 0.8 mg/ml geneticin, 100 i.u./ml penicillin and 100 µg/ml streptomycin in a humidified air/CO<sub>2</sub> (19:1) atmosphere. Before ECE assay the medium was replaced by 0.5 ml DMEM-HBSS 1:1, 10 mM HEPES pH 7.0 supplemented with 0.1% (w/v) BSA. The inhibitors were added in DMSO at a final concentration of 1 %. The enzyme reaction was started by the addition of 0.42 µM human big ET-1 and  
15 performed for 1.5 hours at 37°C in an incubator. At the end of incubation, the incubation medium was quickly removed and aliquots were analysed by radioimmunoassay for produced ET-1 as described above.

The ECE screening assay was validated by the measurement of the characteristic  
20 inhibitor constants of phosphoramidon ( $IC_{50}$   $0.8 \pm 0.2$  µM) and CGS 314447 ( $IC_{50}$   $20 \pm 4$  nM) [De Lombaert, Stephane; Stamford, Lisa B.; Blanchard, Louis; Tan, Jenny; Hoyer, Denton; Diefenbacher, Clive G.; Wei, Dongchu; Wallace, Eli M.; Moskal, Michael A.; et al. Potent non-peptidic dual inhibitors of endothelin-converting enzyme and neutral endopeptidase 24.11. Bioorg. Med. Chem. Lett. (1997), 7(8), 1059-1064]. The two  
25 inhibitors were measured with  $IC_{50}$  values not significantly different from those described in the literature but measured with different assay protocols. In the cell based assay phosphoramidon showed an  $IC_{50}$  of 4 µM. This assay gave additional information about the inhibitory potency of inhibitors under much more physiologic conditions, as e.g. the ECE was embedded in a normal plasma membrane environment. It is important  
30 to state, that the screening assay was performed in the presence of 1 µM Thiorphan to block any potential big ET-1 degradation due to the action of NEP24.11. No NEP

activity was present in MDCK-ECE-1c transfected cells in preliminary experiments when ET-1 production was measured in presence or absence of thiorphan. In subsequent experiments no thiorphan was added in the incubation medium.

According to the above methods, the compounds of the present invention show  
5 IC<sub>50</sub> values in the radioimmunoassay (E on ECE-inhibition) of about 5 nM to about 1000 µM. The preferred compounds show values of 5 nM to 1000 nM.

As mentioned earlier, medicaments containing a compound of formula I are also an object of the present invention as is a process for the manufacture of such medicaments, which process comprises bringing one or more compounds of formula I  
10 and, if desired, one or more other therapeutically valuable substances into a galenical administration form.

The pharmaceutical compositions may be administered orally, for example in the form of tablets, coated tablets, dragées, hard or soft gelatin capsules, solutions, emulsions or suspensions. Administration can also be carried out rectally, for example  
15 using suppositories; locally or percutaneously, for example using ointments, creams, gels or solutions; or parenterally, for example using injectable solutions.

For the preparation of tablets, coated tablets, dragées or hard gelatin capsules the compounds of the present invention may be admixed with pharmaceutically inert, inorganic or organic excipients. Examples of suitable excipients for tablets, dragées or  
20 hard gelatin capsules include lactose, maize starch or derivatives thereof, talc or stearic acid or salts thereof.

Suitable excipients for use with soft gelatin capsules include for example vegetable oils, waxes, fats, semi-solid or liquid polyols etc.; according to the nature of the active ingredients it may however be the case that no excipient is needed at all for soft gelatin  
25 capsules.

For the preparation of solutions and syrups, excipients which may be used include for example water, polyols, saccharose, invert sugar and glucose.

For injectable solutions, excipients which may be used include for example water, alcohols, polyols, glycerin, and vegetable oils.

- 41 -

For suppositories, and local or percutaneous application, excipients which may be used include for example natural or hardened oils, waxes, fats and semi-solid or liquid polyols.

The pharmaceutical compositions may also contain preserving agents  
5 antioxidants, solubilising agents, stabilizing agents, wetting agents, emulsifiers, sweeteners, colorants, odorants, salts for the variation of osmotic pressure, buffers, coating agents or antioxidants. They may also contain other therapeutically valuable agents.

The dosages in which the compounds of formula I are administered in effective  
10 amounts depend on the nature of the specific active ingredient, the age and the requirements of the patient and the mode of application. In general, dosages of 0.1-100 mg/kg body weight per day come into consideration, although the upper limit quoted can be exceeded when this is shown to be indicated.

### 8.1. General procedure for the cleavage of PMB-thioethers

To 1 eq of the PMB thioether in TFA (15-30 ml/mmol) are added 10 eq triethylsilane at RT and the solution is heated to 80°C for 1 min – 2 h or stirred at RT

for 2 days, recooled and concentrated in vacuo. Standard workup and purification by flash chromatography yields the corresponding thiols.

### 9.1. Trityl deprotection for single compounds with triethylsilane

5 A solution of 0.58 mmol tritylsulfanyl in 5.8 ml TFA is treated at 0°C with 0.92 ml (5.78 mmol) triethylsilane and after 10-30 min at RT evaporated and purified by flash chromatography on silicagel or precipitated from Et<sub>2</sub>O or Et<sub>2</sub>O/pentane to give the thiol-compound.

### 9.2.: Trityl deprotection for single compounds with triisopropylsilane

10 A solution of 2.84 mmol trityl-protected compound in 30 ml CH<sub>2</sub>Cl<sub>2</sub> is treated at 0°C with 8 ml TFA and 5.82 ml (28 mmol) triisopropylsilane. After 30 min at RT the solution is completely evaporated and the compound precipitated twice from Et<sub>2</sub>O/pentane or purified by flash chromatography on silicagel to give the thiol.

15

### 9.3. Trityl deprotection for parallel synthesis:

## 24.2. Ketones and alcohols: b) Solid Phase Synthesis

Preparation of the resin:

### A) Building block synthesis

5        (2S,4R)-4-(4-Methoxy-benzylsulfanyl)-pyrrolidine-1,2-dicarboxylic acid 1-tert-butyl ester (19.48 g, 53 mmol) was treated with TFA (80 ml) in  $\text{CH}_2\text{Cl}_2$  (120 ml) for 15 min. The reaction mixture was concentrated under reduced pressure and the resultant dark red oil was triturated in diethyl ether/n-hexane (1:4 v/v, 860 ml). The precipitated salt was collected and dried under reduced pressure (18.9 g) and directly used in the next step.

10        The TFA salt (18.9 g, 53 mmol) of (2S, 4R)-4-(4-methoxy-benzylsulfanyl)-pyrrolidine-2-carboxylic acid in 1,4-dioxane/ $\text{H}_2\text{O}$  (300 ml) containing  $\text{NaHCO}_3$  (17.8 g, 212 mmol) was treated with Fmoc-OSu (19.7 g, 58.3 mmol) and magnetically stirred for 16 h. The reaction mixture was diluted with water (400 ml) and washed with diethyl ether (2x). Ethyl acetate (400 ml) and HCl (25%, 50 ml) were added. The organic phase was  
15        extracted and washed  $\text{H}_2\text{O}$ , NaCl sat. and dried  $\text{MgSO}_4$ . Filtration and concentration under reduced pressure yielded a foam (22.5 g).

      The above foam (20.7 g, 42.3 mmol) was dissolved in TFA (350 ml) and triisopropylsilane (43.5 ml) was added. The mixture was refluxed for 0.5 h and concentrated under reduced pressure. Diethyl ether (100 ml) and n-hexanes (300 ml) were  
20        added yielding a precipitate. The supernatant was decanted and the precipitate was dried under reduced pressure and high vacuum to yield a white foam (2S, 4R)-4-sulfanyl-1-(fluorenylmethoxycarbonyl)-pyrrolidine-2-carboxylic acid (9.6 g, MS: 370  $\text{MH}^+$ ).

### B) Resin Derivatization

25        The linker 4-(alpha,alpha-diphenylhydroxymethyl)benzoic acid (18.3 g, 60 mmol) was activated using TPTU (17.8 g, 60 mmol), DIEA (30.8 ml, 180 mmol) in DMF(abs., 250 ml) for 3 min. The mixture was added to a flask containing benzhydrylamine resin (loading- $\text{NH}_2$  0.9 mmol/g, 44.4 g) and the flask was shaken for 1 h. The resin was collected on a filter and washed (3 x alternating DMF/isopropanol),  $\text{CH}_2\text{Cl}_2$ , ether and dried: 54.65  
30        g, 0.65 mmol/g (loading based on mass increase).

- 139 -

To the CH<sub>2</sub>Cl<sub>2</sub> washed resin above (46.9 g, 30 mmol), was added a mixture of (2S, 4R)-4-sulfanyl-1-(naphthalene-2-sulfonyl)-pyrrolidine-2-carboxylic acid 12.2 g, 36 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (abs. 550 ml), TFA (80 ml). The red colored mixture was shaken for 1.5 h and the resin was then filtered, washed (3 x alternating CH<sub>2</sub>Cl<sub>2</sub>/isopropanol), CH<sub>2</sub>Cl<sub>2</sub>, ether and dried: 42 g, 0.65 mmol/g (loading based on mass increase).

To the CH<sub>2</sub>Cl<sub>2</sub> washed resin above (33.5 g, 22 mmol), was added a mixture of (2S, 4R)-4-sulfanyl-1-(fluorenylmethoxycarbonyl)-pyrrolidine-2-carboxylic acid (9.7 g, 26 mmol) in CH<sub>2</sub>Cl<sub>2</sub> (abs. 450 ml), TFA (67 ml). ## FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

Continuation of Box I.2

Claims Nos.: 12,44

The initial phase of the search revealed a very large number of documents relevant to the issue of novelty. So many documents were retrieved that it is impossible to determine which parts of the claim(s) may be said to define subject-matter for which protection might legitimately be sought (Article 6 PCT). For these reasons, a meaningful search over the whole breadth of the claim(s) is impossible. Consequently, the search has been restricted to the compounds of formula (I), wherein X is -SO<sub>2</sub>-, -CO-, -SO<sub>2</sub>NH- or -C(O)NR<sub>13</sub>.

The scope of claim 44 is not clear.

The applicant's attention is drawn to the fact that claims, or parts of claims, relating to inventions in respect of which no international search report has been established need not be the subject of an international preliminary examination (Rule 66.1(e) PCT). The applicant is advised that the EPO policy when acting as an International Preliminary Examining Authority is normally not to carry out a preliminary examination on matter which has not been searched. This is the case irrespective of whether or not the claims are amended following receipt of the search report or during any Chapter II procedure.
